

TeachDB: A Person-Specific Memory Layer Framework

The Foundational Architecture for "Kenjindo" (House of Wisdom)

Abstract: TeachDB is a framework designed to construct Person-Specific Memory Layers. By decoupling long-term cognitive provenance from general-purpose Large Language Models (LLMs), TeachDB enables the creation of persistent, evolving knowledge repositories for individuals. This architecture serves as the core component of Kenjindo—a digital library where users engage in dialectical learning with the reconstructed cognitive frameworks of history's thinkers.

1. The Problem

Current LLMs (GPT, Gemini, etc.) provide exceptional reasoning capability but lack persistent, individual-specific depth. When asked about a specific thinker's perspective, they rely on generalized training data that often misses the nuance, axioms, and evolving reasoning paths of that individual. Furthermore, existing RAG systems are retrieval-centric, often failing to synthesize the *logic* behind an individual's unique thought processes.

2. System Architecture: Role Decoupling

TeachDB does not replace LLMs; it augments them by providing an expert-level, person-specific context.

LLM (Inference Engine) General reasoning, linguistic fluency, and task completion.	TeachDB (Memory Layer) Structured reasoning patterns, axioms, and cognitive evolution of a specific person.
--	---

3. TeachDB vs. Existing Technologies

Technology	Role
RAG	Retrieves documents based on keyword/semantic similarity.
Knowledge Graphs	Maps entities and relations.
TeachDB	Synthesizes reasoning logic and cognitive evolution as a dynamic Memory Layer.

4. The Vision: Kenjindo (House of Wisdom)

TeachDB is the engine behind *Kenjindo*, a digital ecosystem where the cognitive architectures of historical figures, scientists, and philosophers are immortalized as independent Memory Layers. Users will not simply "query" these figures; they will engage in structured dialogue, experiencing a collaborative learning environment that evolves as the Memory Layer is queried and refined.

5. Implementation Approach

- **Reasoning Extraction:** Parsing an individual's corpus (writings, recorded talks) into logical primitives.
- **Memory Evolution:** A continuous update loop that incorporates new insights while maintaining consistency.
- **Model-Agnostic Integration:** TeachDB acts as an API-first memory service, compatible with any LLM inference engine.

6. Roadmap and Research Questions

We invite researchers and partners to explore the scalability of "Memory Layering" and the ethics of cognitive reconstruction. Our goal is to set the standard for how personalized cognitive knowledge is stored, retrieved, and applied in the era of Artificial Intelligence.
